1 Introduction

We've already used Structure (Pritchard et al., 2000), the program that uses multi-locus genotype data and MCMC to perform individual assignment for population genetics analysis.

- 1. Let's try to use it with a wrapper package in R!
- 2. strataG (Archer et al. 2016) is a toolkit for haploid sequence and multilocus genetic data summaries, and analyses of population structure.
- 3. Let's look at some assumptions: are populations of equal size (Wang 2016)

1.1 Installation

- Please install Structure v2.3.4 package WITHOUT FRONT END from here http://pritchardlab.stanford.edu/structure_software/release_versions/v2.3.4/html/structure.html
- You will need to know the path of where you have installed the files.

- Add this path to the PATH system variable on your machine. OS specific instructions here: https://www.java.com/en/download/help/path.xml
- Install the *strataG* package in R, install the *installr* package in R. Call both libraries using the *library()* function
- Check that your path is listed in your system by using the *system.PATH()* function in R (from *installr* library).

2 Getting Started

Let's get our data in shape.

- Call the *adegenet* library, and use the same *read.structure()* code from project 2 (repens.stru) to import the repens data.
- ullet You will now have a "genind" object. We need to convert this to a "gtypes" object for strataG
- Use the function genind2gtypes() to create a new gtypes object.
- Look at the structure of this object.

3 Using Structure

To actually use structure, use the *structureRun()* function

3.1 Running Structure

- Make sure you use ?structureRun to look at the function's help page
- Assign function output to a new object called, for instance, "default_output"
- Use a k.range of 2:16 (for sake of time)
- Set num.k.rep equal to 2
- label = "default"
- Use default burnin and numreps

3.2 Evanno et al.

Now let's look at some output

- Use the evanno() function to look at Evanno et al. plots for the default_output
- Choose value(s) of K to look at
- Make Structure barplots for Ks of interest using the *structurePlot()* function (Hint: look at the structure of your "default_output" object)

3.3 Alternative prior

Let's take Wang (2016)'s advice into account

- To change settings to switch to separate alphas, we need to change the extraparams file
- Nora has edited the function and made new function called runStructureAlt() in a separate R file
- Run the code to write this function.
- Run this function using same settings as above, name it "alt_output"
- label = "alt"
- Make Evanno plots, look at barplots

Compare outputs, in terms of inferred K
